WATER LEVELS AND ARTESIAN PRESSURES  
IN  
OBSERVATION WELLS IN MONTANA  
THROUGH 1967

by

T. E. Reed and R. G. McMurtrey

INTRODUCTION

A continuing program of systematic collection of records of water levels in selected observations wells has been made part of a program for the investigation of the ground-water resources of Montana by the U.S. Geological Survey in cooperation with the Montana Bureau of Mines and Geology. This report is the second in a series of annual reports of water-level records for all permanent observation wells in Montana. It includes all data published in the first report of the series and data for 38 additional wells. Future reports will be organized so that the report for each fifth year will be a compilation of the previous 5 years. The 5-year periods will end on years divisible by 5 (1970, 1975, 1980). A report may contain 1 to 5 years of data, depending on which year it is written. For example, the 1968 report will cover 3 years of data (1966-68), the 1970 report 5 years (1966-70), the 1971 report 1 year (1971), and the 1975 report 5 years (1971-75).

The intent of the water-level measurement program is to provide long-term continuous records of fluctuations of the water level in representative wells in the various aquifers throughout the state. Recognized uses of such records are: (1) to facilitate the prediction of trends in ground-water levels that indicate changes in storage; (2) to serve as a framework to which shorter records from project studies may be related; (3) to aid in prediction of base flow of streams; (4) to appraise the relationship between water-level fluctuations and precipitation, pumping, and other factors; (5) to identify areas of detrimentally low or high ground-water levels; and (6) to provide

information for use in basic research. Records for the foregoing and other uses need to be compiled and published in a manner that will assure their current and future availability.

The systematic collection of data on ground-water levels in Montana was begun in 1947 under a federal program to develop a nationwide observation-well network. It continued under this program until 1964, when state funds were made available through the State Engineer to expand the network. In 1965 the observation-well network was made a part of the cooperative ground-water program of the Montana Bureau of Mines and Geology. Before 1956, water-level measurements were published annually by the U.S. Geological Survey as water-supply papers. Since 1956, the records of water levels in the federal network of observation wells have been published in 5-year increments. Those water-supply papers in which measurements of water levels in federal observations wells in Montana have been published are listed in Table 1.

Table 1. --U. S. Geological Survey Water-Supply Papers in which water-level measurements in federal observation wells in Montana have been published.

Year	Water-Supply Paper	Year	Water-Supply Paper
1935	777	1948	1130
1936	817	1949	1160
1937	840	1950	1169
1938	845	1951	1195
1939	886	1952	1225
1940	910	1953	1269
1941	940	1954	1325
1943	990	1955	1408
1944	1020	1956-60	1760
1947	1100		

In addition to the permanent observation wells, project observation wells are established in connection with each areal study. Water-level measurements made periodically in these wells are published in project reports. When a study is completed, selected project observation wells are added to the network of permanent observation wells. Figure 1 shows study areas in Montana for which reports that contain periodic water-level measurements have been published. References for the reports are keyed to the numbers shown on Figure 1 and are listed in the "References cited".

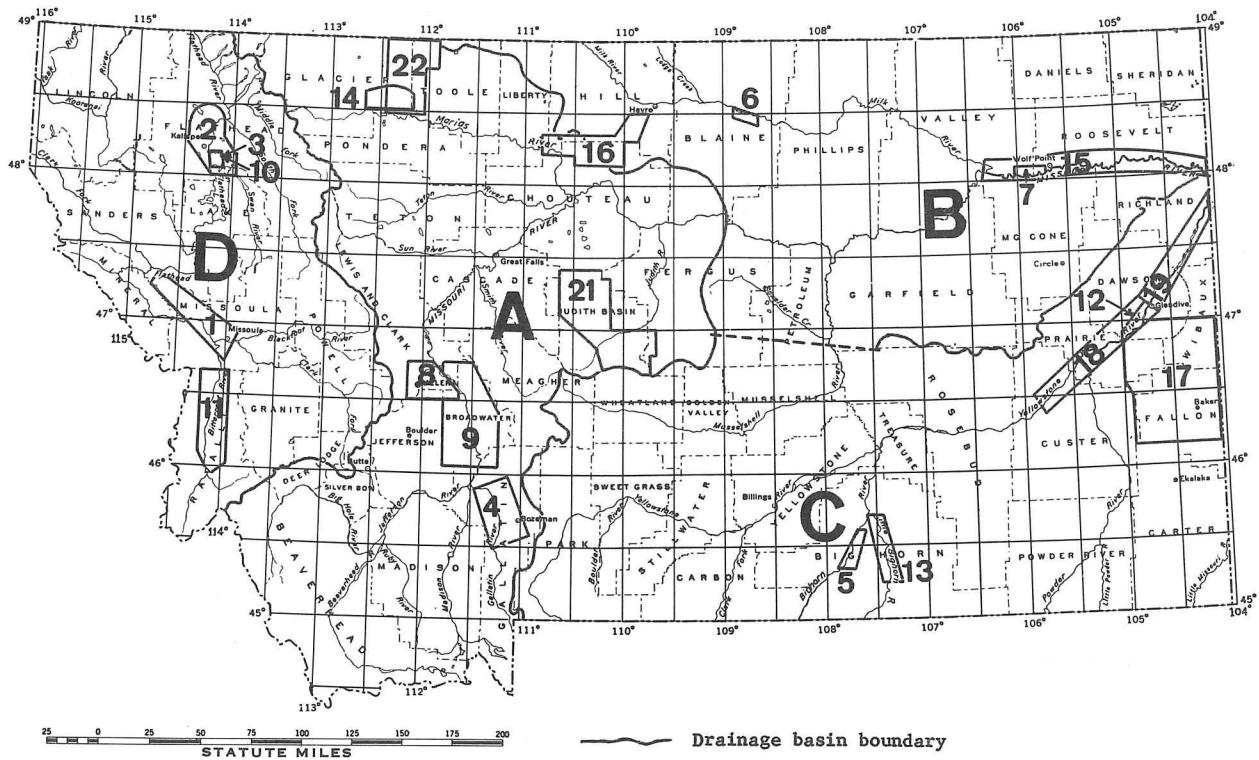

Figure 1. --Drainage basins and areas for which project reports contain periodic water-level measurements. (Numbers correspond to the report reference number shown in "References Cited"; letters show drainage basins: A, upper Missouri; B, lower Missouri; C, Yellowstone, upper Musselshell, and Little Missouri; and D, Columbia.)

Figures 2, 3, 4, and 5 show the location of wells for which records are included in this report, and Table 2 contains water-level measurements for each of the wells, except federal observation wells, through the 1967 water year. Water-level measurements in the federal observation wells are included from January 1961 through the 1967 water year. The measurements are published on the basis of the water year to facilitate comparison with streamflow records. The water year is the 12-month period ending September 30 of each year. It is designated by the calendar year in which it ends. Thus, the year that ends September 30, 1967, is called the 1967 water year.

#### DESCRIPTION OF WELLS

The tabulation of water-level data is preceded by a description of the well (Table 2). Each well is assigned a number based on its location within the system of land subdivision used by the U. S. Bureau of Land Management. The well number shows the location of the well by quadrant,

township, range, section, and position within the section. A graphic illustration of this method of well numbering is shown in Figure 6. The first letter of the well number gives the quadrant of the Montana principal meridian and base-line system in which the well is located. The first numeral indicates the township, the second the range, and the third the section in which the well is located. Lowercase letters that follow the section number show the location of the well within the quarter section (160-acre tract) and the quarter-quarter section (40-acre tract). These subdivisions are designated a, b, c, and d in a counterclockwise direction, beginning in the northeast quadrant. If two or more wells are located within the same 40-acre tract, consecutive digits beginning with 1 are added to the well number. For example, well B-9-20-21ad1 is in the  $SE\frac{1}{4}$   $NE\frac{1}{4}$  sec. 21, T. 9 N., R. 20 W., and is the first well inventoried in that 40-acre tract.

The well number is followed by the owner's name, the type of well (water-table or artesian), and the geologic setting or geologic formation. The diameter is reported in inches (in.) and the depth in feet (ft.) below land-surface datum (lsd). All levels are read from a measuring point (MP) which is related to either lsd or mean sea level (msl). Altitude of MP, where known, is given in feet above msl. Water levels are in feet below lsd, except where a plus (+) sign indicates a level above lsd.

## OCCURRENCE OF GROUND WATER

The initial source of most ground water is precipitation, which varies widely over Montana. The averages for the seven climatological divisions set up by the U. S. Weather Bureau in the state range from 13.07 inches in the north-central division to 19.04 inches in the western division. The lowest long-term average at an individual station is 9.79 inches, and the highest is 34.38 inches; however, seven of nine seasons at a station in Glacier National Park have produced totals of more than 100 inches. Much of the water from precipitation returns to the atmosphere by evaporation or transpiration or flows overland; part seeps into the soil zone and percolates downward to the underground reservoirs. Water in these reservoirs occurs in open spaces known as voids, interstices, pore spaces, joints, fractures, or solution channels in the rocks mantling the state. The size, shape, character, and distribution of the open spaces determine, to a great extent, the occurrence of ground water. The open spaces are generally interconnected and act as minute conduits through which the water moves laterally at a slow rate until it is discharged to the earth's surface through springs, wells, and effluent streams, or to the atmosphere by evaporation and plant transpiration. Under natural conditions, over a long period of time, the amount of water that is added to ground-water storage is in approximate equilibrium with the amount that is discharged.

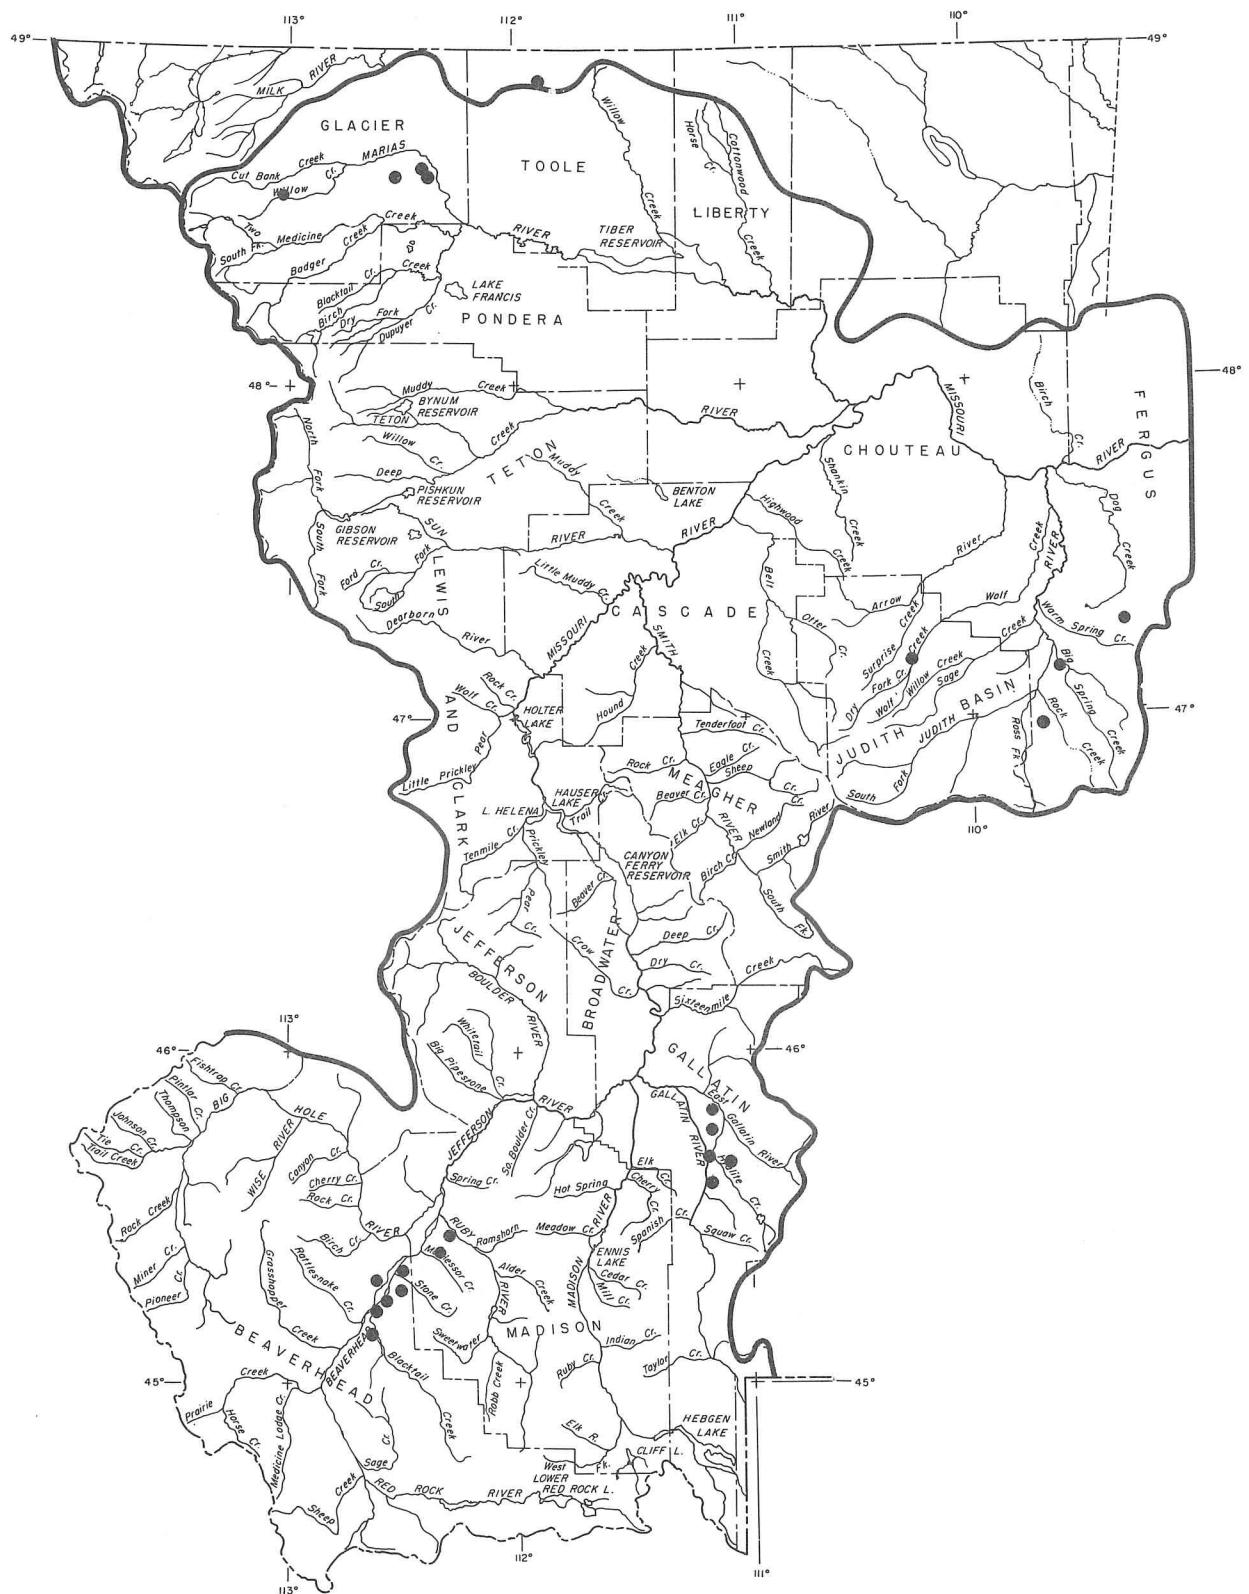

Figure 2. --Map showing location of observation wells in upper Missouri River drainage area.

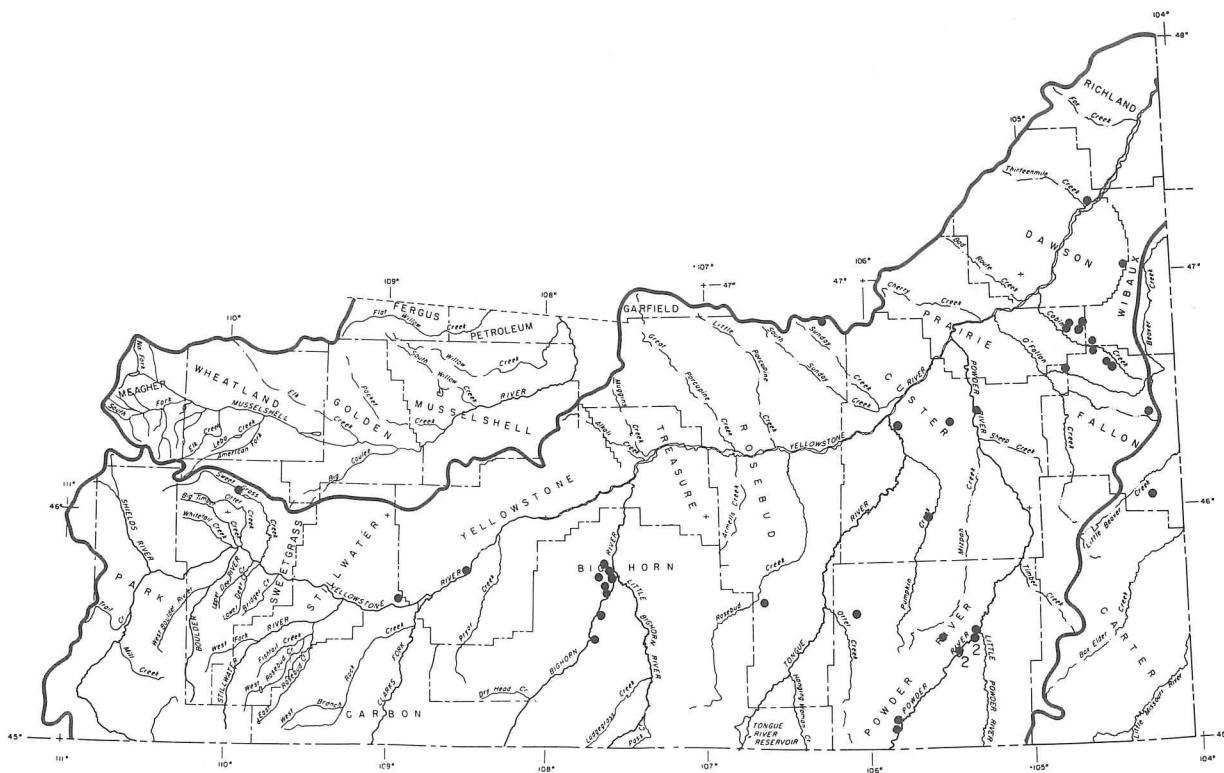

Figure 4. --Map showing location of observation wells in Yellowstone, upper Musselshell, and Little Missouri River drainage areas.

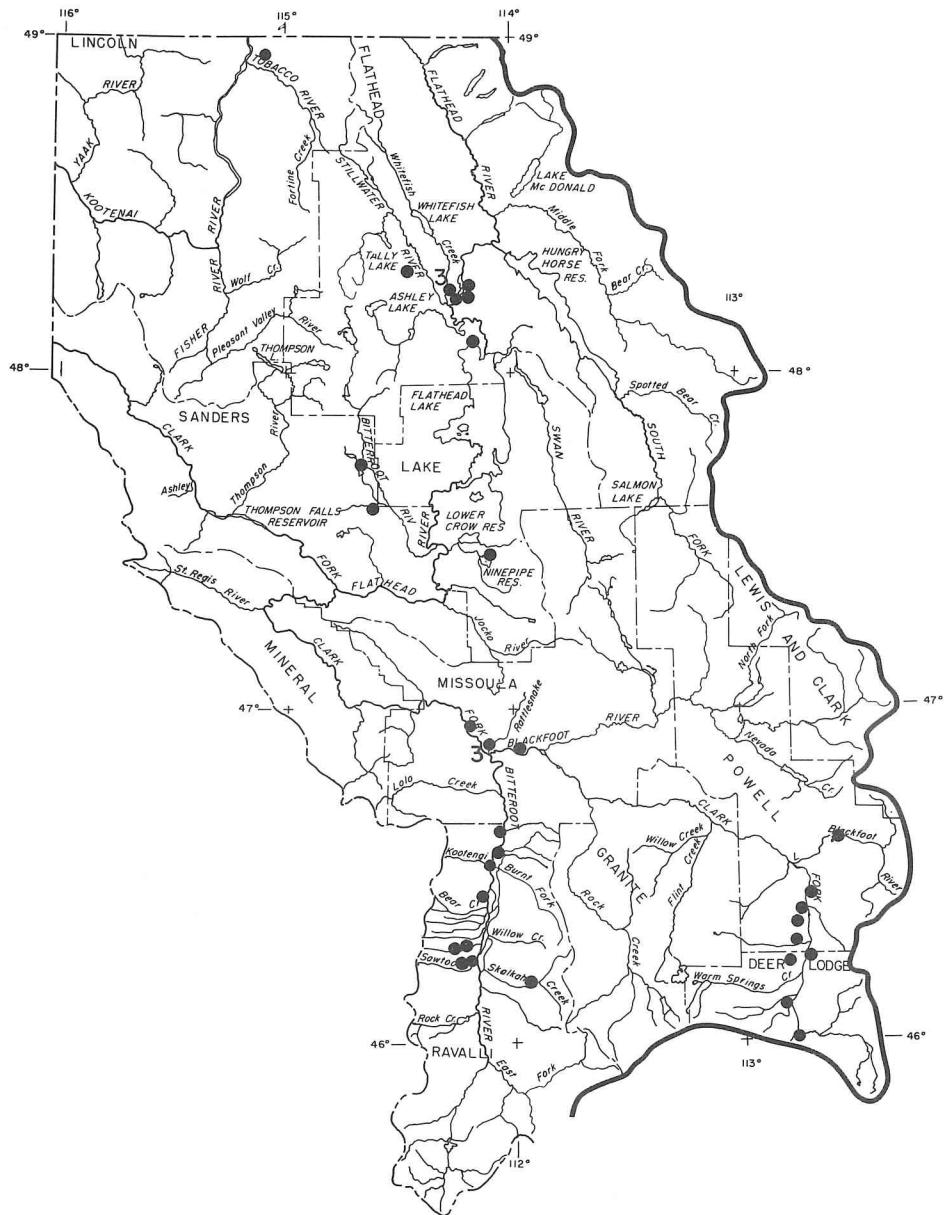

Figure 5.--Map showing location of observation wells in Columbia River drainage area.

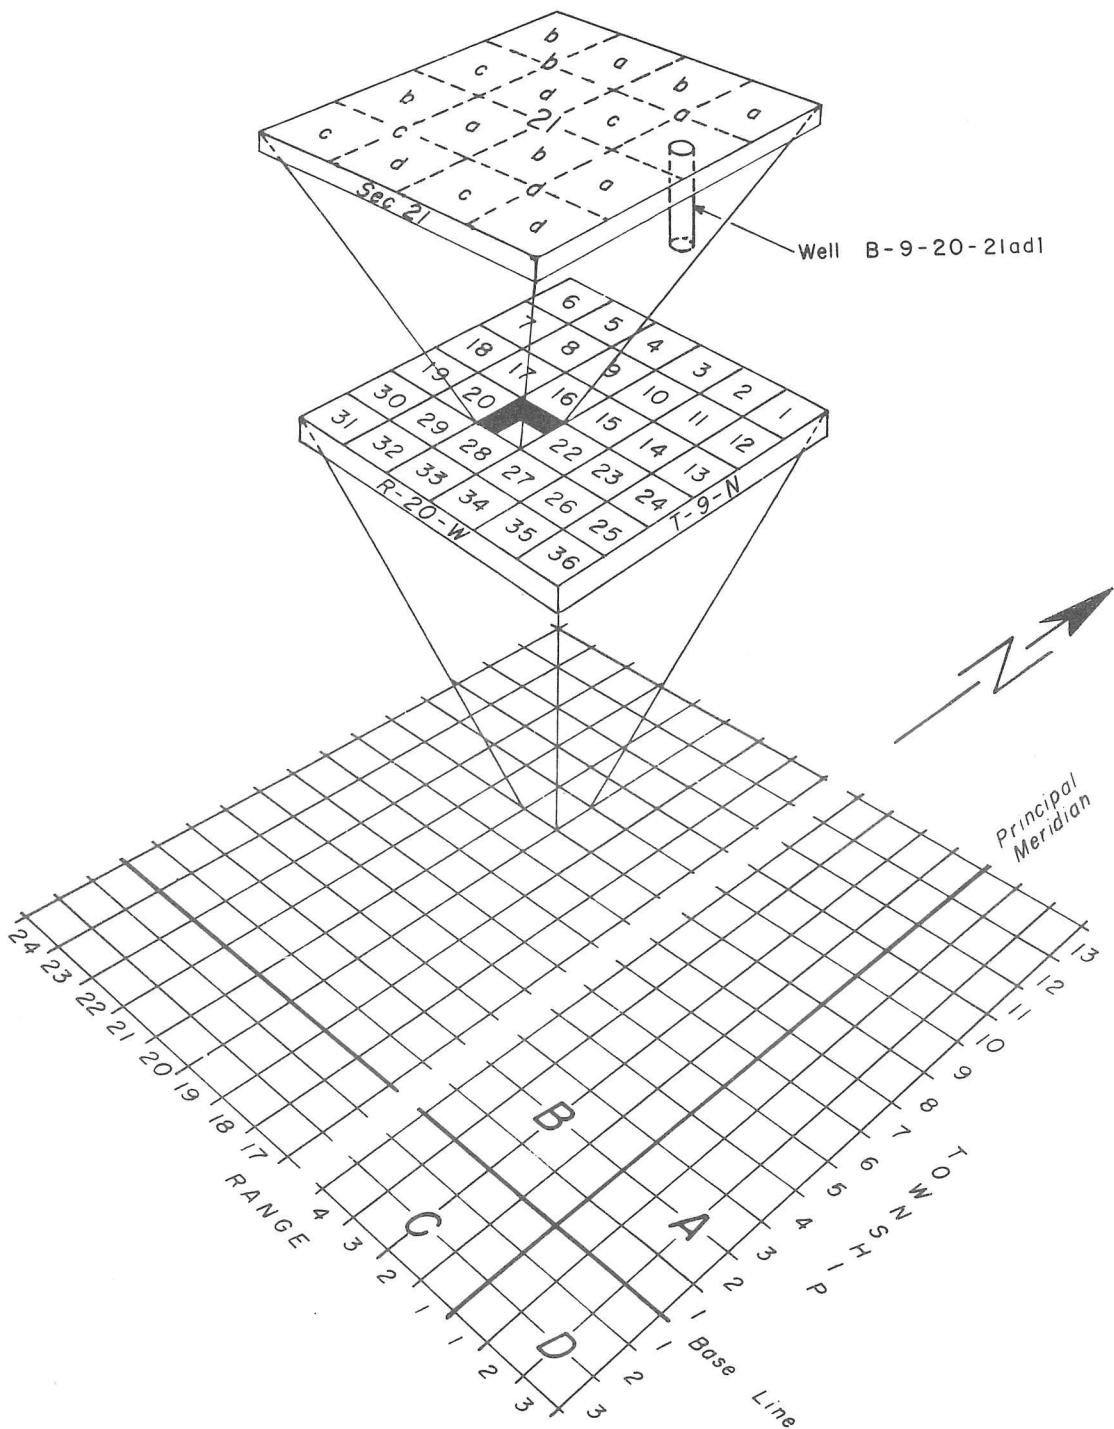

Figure 6.--Sketch showing well-numbering system.

Ground water in Montana occurs under a wide range of conditions and in varying degrees of usefulness. Throughout most of the state it can be obtained from wells drilled into one or more of the numerous aquifers, but not necessarily at a reasonable cost or in the quantity or of the quality desired. An aquifer is a geologic formation that transmits water in sufficient quantity to supply pumping wells or springs. In some areas of the state, ground water is relatively difficult to obtain, and aquifers yielding only a few gallons of water per minute are of considerable importance. In other areas where aquifers may yield several hundred gallons per minute, formations capable of yielding small amounts may be classed as nonproductive.

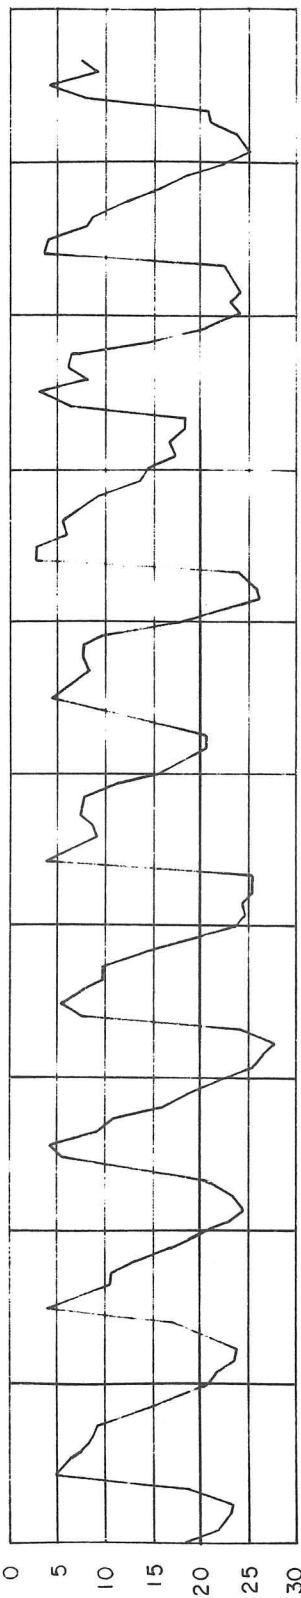

Aquifers may be classified as water-table or artesian. A water-table aquifer is exposed at the surface and contains a saturated zone and an unsaturated zone. The surface within the saturated zone at which the pressure is atmospheric is known as the water table. The water level in a well that is hydraulically connected with the aquifer coincides with the water table. An artesian aquifer is overlain by relatively impermeable material (material through which water does not move readily) and contains water under sufficient pressure to rise above the top of the aquifer if penetrated by a well. If the pressure is sufficient to raise the water above the land surface, a well penetrating the aquifer will flow.

#### F L U C T U A T I O N S O F T H E W A T E R L E V E L

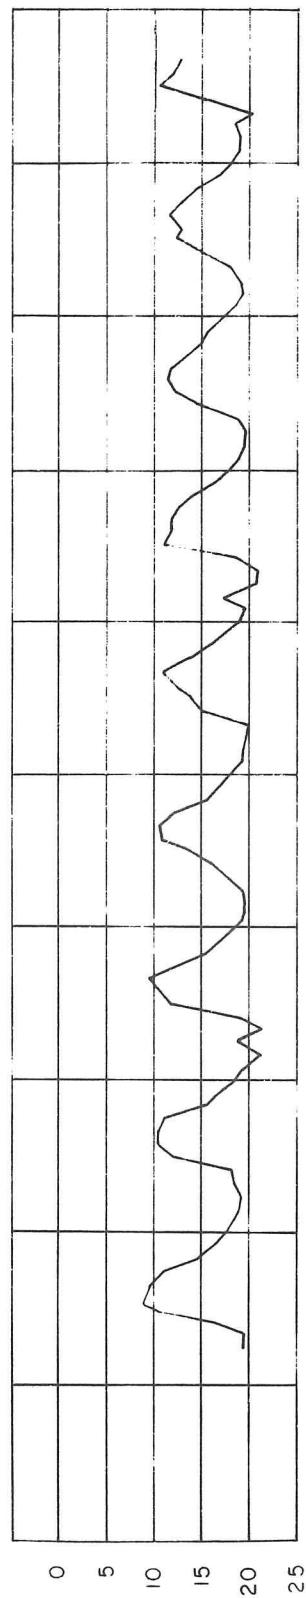

Water levels in wells are almost constantly fluctuating, and may decline or rise a fraction of an inch or many feet in a relatively short time. They are influenced by factors such as seasonal changes in rate of recharge to and discharge from the aquifers, local geology, direct recharge from precipitation, local irrigation practices, pumping from nearby wells, evaporation and transpiration of water by vegetation, and by changes in water levels in nearby lakes, streams, or drains. In artesian wells, changes in water level may occur quickly over large areas as a result of pumping. Temporary influences on the water levels in artesian wells result from changes in atmospheric pressure, earthquakes, earth tides, changes in surface-water stage, and changes in surface loading.

In Montana, water-level fluctuations generally are cyclical, reflecting seasonal changes in the amount of water in storage, which varies because of differences in rates of recharge and discharge (Fig. 7, 8, and 9). The water levels generally rise during the spring and summer and decline during the fall and winter. Long-term trends in water-level fluctuations may be impressed locally on the seasonal cycle. These trends reflect deficient or surplus recharge over a period of years, owing to natural climatic variations or to man-induced variations such as a change in irrigation pattern, land drainage, or pumping from wells.

A-7-47-13dd

Depth to water below land surface, in feet

Figure 8. --Graphs of water levels in wells A-14-16-15bb, A-28-57-28dd, and A-7-47-13dd.

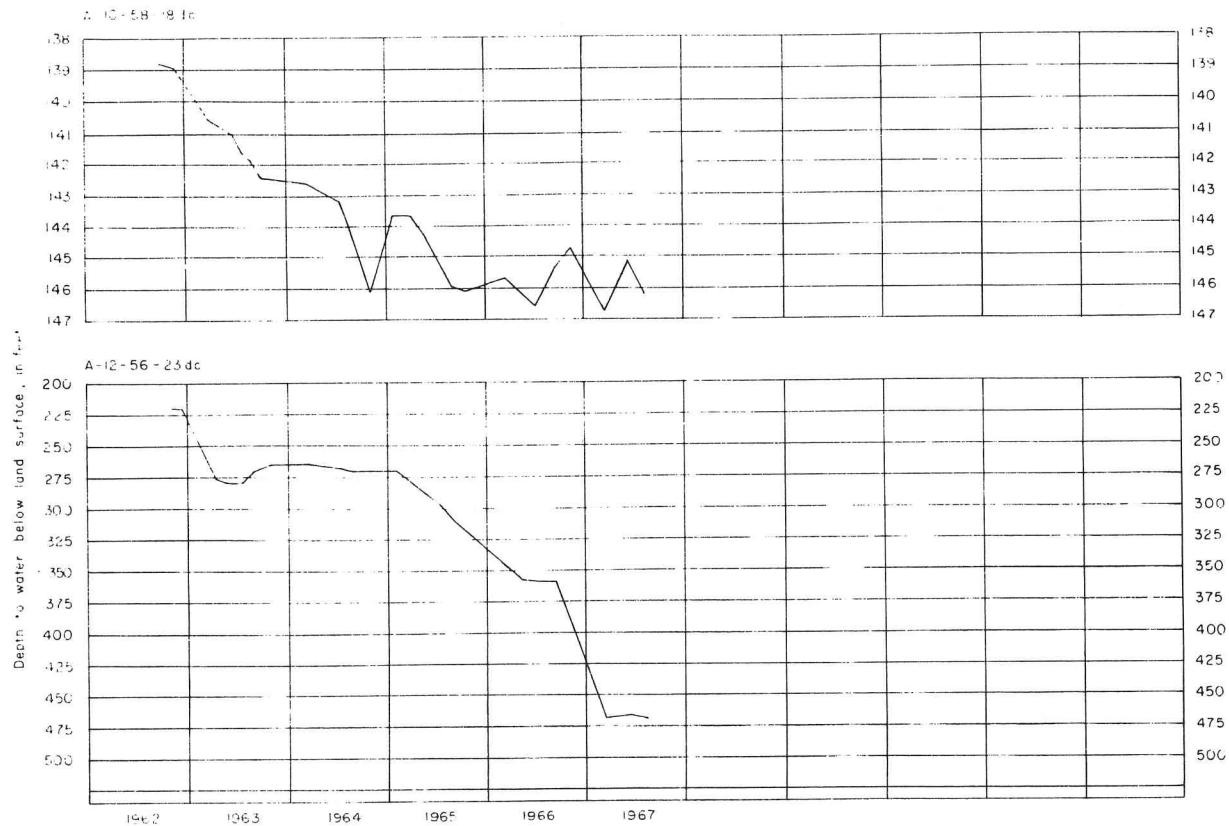

Figure 9. --Graphs of water levels in wells A-10-58-18dc and A-12-56-23dc.

The seasonal trend is illustrated by the graphs of water levels in Figure 7. Two of the wells (B-9-20-21ad1 and B-13-20-14ac) are in intermontane basins of western Montana and the third is in the Yellowstone River basin of eastern Montana. The pattern of water-level fluctuations is similar in all three wells, because water for recharge is available at each well at about the same time. The magnitude of fluctuation differs, owing to differences in the quantity of water available for recharge, the geologic setting of the well, and the permeability of the materials in which the well is drilled.

Trends in water-level fluctuations impressed on the seasonal cycle are shown in Figures 8 and 9. The graph of water-level measurements for well A-14-16-15bb shows sharp peaks caused by heavy precipitation or snowmelt and some sharp lows probably caused by pumping water from the materials in which the well is located. The graph for well A-28-57-28dd shows the effect of above-normal precipitation for 1953-55 and below-normal for 1956-58. Departures from normal precipitation after 1958, however, do not correlate as well with trends shown on the graph. A surplus of recharge from 1957 to 1967 is shown by the graph for well A-7-47-13dd. It is probably caused by increased recharge from irrigation. Pumpage of water from nearby wells is reflected in the graphs for wells A-10-58-18dc and A-12-56-23dc. The magnitude of the lowering of the water levels overshadows any seasonal cycle that may have occurred.
