Spring and Well Inventory for the Powder River and Tongue River Watersheds, Southeastern Montana

Introduction

Production of coalbed methane (CBM) began in Montana during 1998 in the Squirrel Creek drainage near Decker. The potential for CBM production covers portions of southeastern Montana, including an area south of Ashland in ranges 37 east through 48 east (Van Voast and Thale, 2001). Much of the Powder River and Tongue River watersheds are located in an area of potential CBM production. Communities within the project area include Ashland, Birney, Decker, and Broadus. Coal deposits within the area have been used locally since the time the area was first settled. Currently commercial mining of coal includes the Rosebud mine at Colstrip and the Decker and Spring Creek mines near Decker. The potential exists for future development of coal resources in the area for both solid fuel and coalbed methane.

The geology and hydrogeology of the area has been described in numerous reports. Particularly, during coal exploration work and coal-mine impact assessments during the 1970's and 1980's, reports were published that provided extensive background information. The coalbeds in the area have been mapped and studied by investigators from the U. S. Geological Survey and Montana Bureau of Mines and Geology. A list of applicable publications is provided in Appendix A.

Well, Spring, and Water-Rights Information on the Internet

Well and spring data may be obtained from the Montana Groundwater Information Center (GWIC) at url address: <http://mbmggwic.mtech.edu/>. The first time a user enters this database he/she will be asked to create a username. After successfully logging in the user is directed to a query page that allows the user to search by location, site name, subdivision, or county. The location and site name queries will return information on the water-right number (if on-file in GWIC), full site name, location, type of water feature (i.e., well, spring, or pond), total depth, pumping water level, static water level, yield, date drilled, and water use. These data can be downloaded by copying and pasting into a spreadsheet program. The GWIC ID hyperlink will take the user to the well log for that particular well or spring. The county download retrieval will create a zipped file that can be downloaded to the user's computer. Different reports are available for the county download option and include well data, lithology, water quality and field visit reports.

Information and listings of water rights in Montana are available from the regional Montana Department of Natural Resources and Conservation (DNRC) office and may be accessed through the internet in two different ways. To access the data from the DNRC web page the user must type the following url in the address window:
<http://www.dnrc.state.mt.us/wrd/home.htm>. Choose "Water Rights" from the left-hand column. This action will bring the "Water Rights Bureau" page into view. Users may access water rights information by choosing "Water Right Information and Indexes by Region" and selecting a region such as Billings. The water-rights data are downloaded in one of several text formats. The text retrievals include all water rights on file for surface

water, ground water and springs, but they are lengthy as the entire region is included. An alternate method is to choose “NRIS – Water Right Query System” from this same website. This action will direct the user to the Montana State Library Natural Resource Information System website which houses the DNRC Water Right Query System. The url address for this site is <http://nris.state.mt.us/wis/data/waterrights.htm>. From this site users may select water rights information based on county, basin, stream, or owner. Searches on water right numbers and types of water rights are also available. There are two important points to remember when using this site. First, this site is case-specific so the data are only retrievable in upper case; therefore, the Caps Lock button should always be on. Secondly, if the user has a pop-up blocker then the user must hold down the control key along with the mouse when submitting requests for data.

Acknowledgments

The authors wish to acknowledge the assistance and support that was received during this project. Many landowners allowed much welcomed access across their property. The Powder River and Custer conservation districts helped coordinate with landowners, and the U. S. Environmental Protection Agency and the Montana Bureau of Mines and Geology provided financial support. Many of the spring site visits were done by Mr. Monte Smith.

Geology

The Tongue and Powder River watersheds are underlain by continental sedimentary rock of the Paleocene Fort Union Formation. The area is in the northern one-third of the southward-plunging Powder River Basin (Figure 1). The basin extends from near Casper, Wyoming to Miles City, Montana and is bounded on the west by the Big Horn uplift, on the east by the Black Hills uplift, and on the north by the Miles City Arch. The sedimentary beds are gently dipping. The axis of the Powder River Basin roughly parallels the Tongue River from the Montana – Wyoming state line to Miles City. The land surface slopes generally downward toward the north, consequently the youngest rock units are exposed at the surface in the southern part of the region and progressively older beds are exposed toward the north.

The main exposed rock units in the area are interbedded pale yellow to gray sandstone, mudstone, coalbeds, and carbonaceous shale of the Tongue River Member of the Fort Union Formation. Much of the near-surface coal has burned by natural ignition. The burning of the coal has baked and thermally metamorphosed the overlying sediments, forming clinker beds of variable thickness. The orange-red clinker beds often form prominent cliff faces and are used as stratigraphic marker horizons for the surface mapping of coal. Overlying the Fort Union Formation, in the southwest corner of the inventory area, are sandstone and mudstone units of the Eocene Wasatch Formation.

Strippable coal resources in southeastern Montana total more than 32,000,000,000 tons (Matson and Blumer, 1973). In some areas the correlations of coal beds have

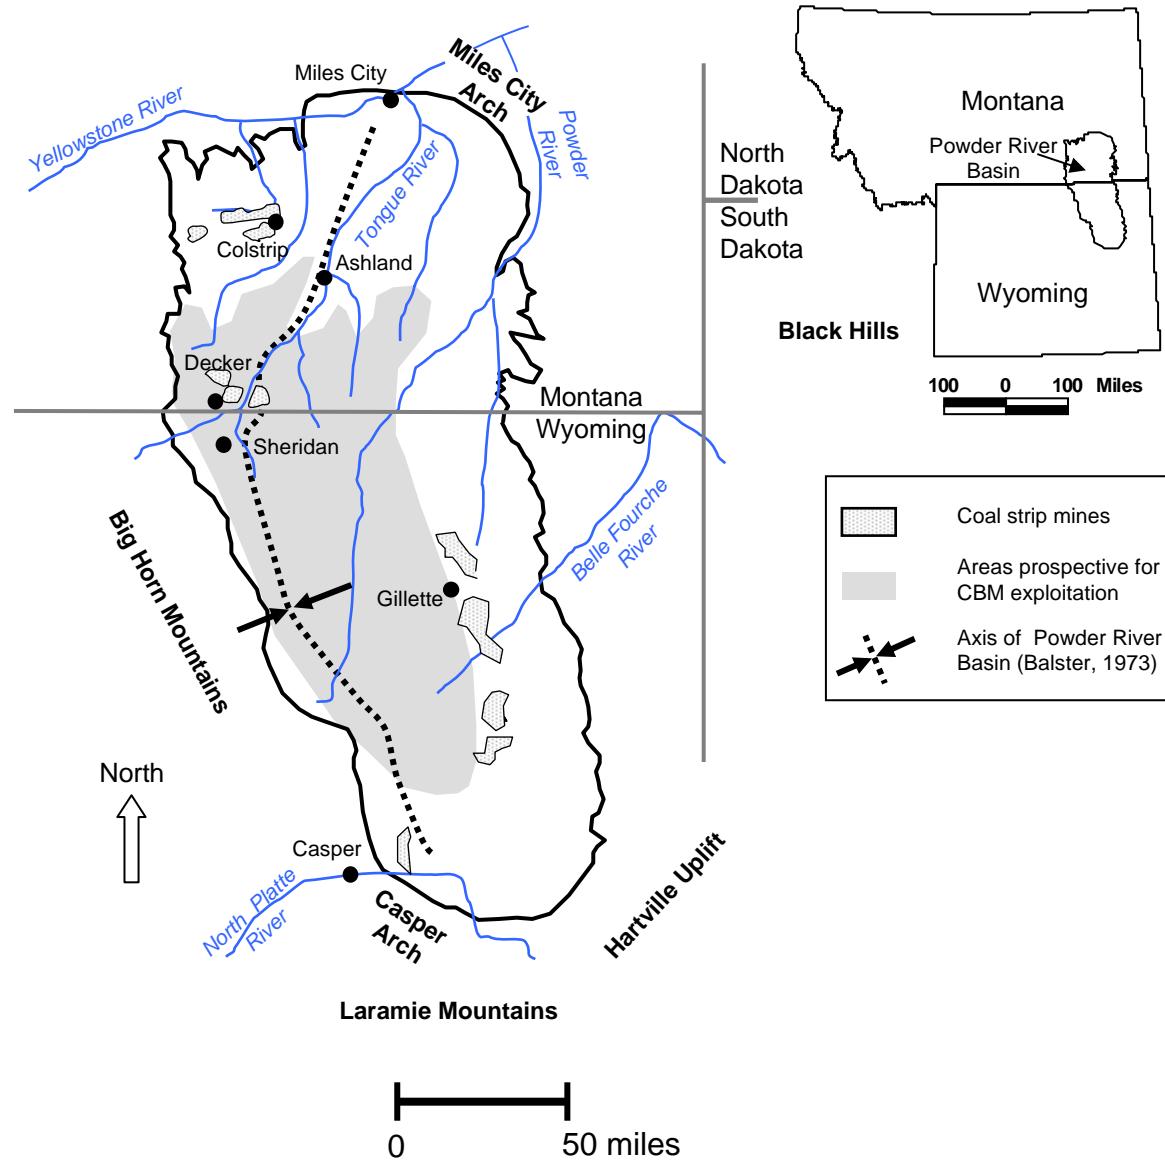

Figure 1. The Powder River Basin is in southeastern Montana and northeastern Wyoming. Vast quantities of coal and coalbed methane exist in the Fort Union Formation within the Basin.

been well defined by previous investigators. In other areas the correlation is ambiguous at best. The lowest principle coal bed in the Tongue River Member is the Knobloch and the upper-most is the Anderson. The intervening section is approximately 1,000 feet thick (Heffern and others, 1993).

Field Procedures

An inventory of springs and wells within the area began in May, 2001 and continued through November, 2003. Letters were sent to landowners, and announcements published by the conservation districts, inviting landowners to provide locations of springs they wished to have inventoried. Site visits were scheduled with interested landowners. Springs were not inventoried on private land if the landowner did not request a site visit.

Springs located on public land were identified according to responsible government agency (U. S. Bureau of Land Management and Montana Department of Natural Resources and Conservation). A separate inventory of springs on U. S. Department of Interior Forest Service was conducted and released as a data report (Donato and Wheaton, 2004).

Each site was visited and, where possible, physical and chemical attributes were measured and noted where flow was observed. Spring discharge rates were determined by the bucket-stopwatch (volumetric) method, and specific conductance and temperature were measured using hand-held field meters. Latitude and longitude coordinates were

determined for each site using a hand held, navigational GPS unit. The area surrounding the site was inspected and notes made on geologic associations and the nature and condition of any development as appropriate.

Database

Hydrogeologic data are presented in one plate and two appendices, and are stored in the Montana Ground-Water Information Center (GWIC) database (<http://mbmggwic.mtech.edu/>). A GIS compilation of spring and well locations, geology, coal and clinker outcrops and subcrops, forest boundary, roads, and drainages is shown on Plate 1. Appendix A is a bibliography of coal and methane publications relevant to Montana. Appendices B and C contain data collected during the 2001 through 2003 field seasons. The physical and chemical attributes of the springs and catchments, including criteria to assess vulnerability to mining or gas development, are in Appendix B; data for the inventoried wells are in Appendix C.

Locations for sites are recorded by latitude and longitude, and by township, range, section and tract. Tracts are identified by the letters A, B, C, and D, with A being the northeast quarter section and continuing counterclockwise so that D is the southeast quarter. Quarter sections are designated first, quarter-quarter sections second, and so forth. It is important to note that the location system used here is reversed from that commonly used by land surveyors; here, the letter designations begin with the largest quarter and progress to smaller ones. With the quarter-quarter system used by surveyors,

the tract designation DABC would be read backwards as the southwest quarter, of the northwest quarter, of the northeast quarter, of the southeast quarter.

Spring Hydrology

Springs typically issue from clinker beds, coal beds and sandstones near their contacts with underlying mudstone or shale units. In valleys the sources of springs are commonly obscured by alluvial or colluvial deposits. Aquifers that support springs are recharged along topographically high ridges covered by clinker, where stream channels cross subcrops and in areas of outcrop. In the Powder River and Tongue River watersheds there are both local and regional ground-water flow systems. Locally recharged springs may respond fairly quickly to weather patterns by exhibiting lower flow during droughts and increased flow during wet years. Some of the more persistent springs in the area are likely fed by ground water migrating along regional flow paths and discharging at the surface where the aquifer beds are exposed by erosion.

Ground-water quality can be used to identify regional flow paths. Regional ground water in the Powder River Basin has a moderate TDS content and is chemically very soft. Therefore, springs having TDS values in the range of 1,500 to 2,000 mg/L, and Ca plus Mg hardness values less than about 100 mg/L may be among springs that have the longest flow paths from recharge areas, perhaps of regional scale.

A total of 279 springs and 133 wells were visited and inventoried (Appendices B and C). Of the 279 springs, 164 had measurable discharge. Discharge rates ranged from 0.01 gpm to 82 gpm. A total of 55 springs had a discharge rate of 1 gpm or greater. Specific conductance values ranged from 123 umhos/cm@25C to 8,640 umhos/cm@25C and pH values ranged from 6.6 to 9.1.

Vulnerability to Development

Of special note on Appendix B are judgments of possible source coalbeds, based on Matson and Blumer (1973) and Van Voast and Thale (2001), and estimated proximities of recharge for each spring. These will be key indicators of spring-flow vulnerability to developments of mining or coalbed methane production. Both types of development are known to disrupt ground-water flow, but differing conditions of topography and geology characteristic of each type can create differing impacts.

In the case of mining, springs having local sources of recharge may be the most vulnerable to nearby development, while those fed by more regional recharge may be less affected. Coal mines operate in areas of lowest overburden and would be comparatively local developments in the rugged terrain of the area. These developments are not likely to penetrate regional flows characteristic of deeper aquifers farther from the outcrop areas.

In the case of coalbed methane development, springs fed by the regional flow system will be the most vulnerable. Methane does not occur in local flow systems

because of the attendant oxidizing conditions commonly evidenced by the presence of sulfate in the ground water. Gas production will be found farther from recharge areas, in deeper aquifers where reducing conditions encourage the stability and growth of methanogenic bacteria. In the Powder River Basin of Montana these conditions are optimum in Townships 8 and 9 South (Van Voast and Thale, 2001), but only moderately favorable in Township 7 South, and other areas within about 35 miles of the Montana-Wyoming state line.

Ongoing Work

All future data derived from landowner and MBMG monitoring and any new spring and well inventories will be added to the GWIC database and made immediately available on line. The data collected during this and other studies (Donato and Wheaton, 2004), (Wheaton and Donato, in press) are being further evaluated and compared to data from the surrounding region. Information obtained from this evaluation will be used to help refine interpretations of the geologic sources of ground water issuing from the springs, and to develop a hydrologic model. Flow measurements and field parameters from approximately 29 spring sites in the Powder River, Tongue River and Rosebud Creek watersheds are being obtained on a monthly basis as part of a basin-wide long-term monitoring program. This information will be used to evaluate impacts from energy development and from natural variations of climate.
